# Temperature and Volume Dependence of the Viscosity of Water and Heavy Water at Low Temperatures

## Kenneth R. Harris\* and Lawrence A. Woolf

School of Physical, Environmental and Mathematical Sciences,<sup>†</sup> University College, University of New South Wales, Australian Defence Force Academy, Canberra, ACT 2600, Australia

New measurements have been made for the viscosity ( $\eta$ ) of light and heavy water between the temperatures of 255.65 K and 298.15 K at pressures up to approximately 375 MPa with a falling-body viscometer. A revised correlation function is used to represent the results as a function of temperature and molar volume (*V*) with a standard deviation of  $\pm 0.2\%$  for both H<sub>2</sub>O and D<sub>2</sub>O. The overall uncertainty is estimated at  $\pm 1\%$ . Comparison of the two sets of data shows that they are consistent with the correlation  $\eta$ (D<sub>2</sub>O, *T*, *V*) = 1.0544 $\eta$ (H<sub>2</sub>O, *T* – 6.498 K, *V*) where 1.0544 is the square root of ratio the molar masses and 6.498 K is the thermal offset proposed by Robinson and co-workers.

#### Introduction

Recently Harris<sup>1</sup> examined the difference between the viscosity and self-diffusion coefficients of water and heavy water at high pressures in terms of the scaling relationship suggested by Robinson and co-workers,<sup>2</sup> the so-called thermal-offset effect. Within experimental precision, the viscosity of heavy water at a given temperature and pressure was found to equal that of ordinary water at a temperature 6.498 K lower and the same pressure, corrected for the difference in molar mass

$$\eta(D_2O, T/K, p) = 1.0544\eta(H_2O, (T - 6.498)/K, p)$$
 (1)

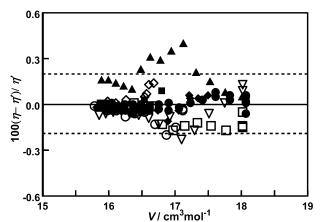

An analogous relation holds for the self-diffusion coefficient

$$D(D_2O, T/K, p) = D(H_2O, (T - 6.498)/K, p)/1.0544$$
 (2)

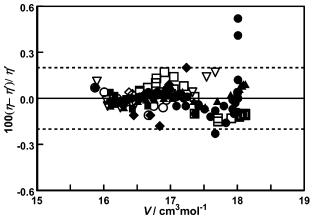

The quantity 1.0544 is the square root of the molar mass ratio of the two isotopomeric forms of water. While the self-diffusion data conformed to eq 2 down to temperatures of -30 °C and up to pressures of 400 MPa, the low-temperature viscosity data (-15 °C to 10 °C) of Jonas and co-workers <sup>3,4</sup> showed considerable scatter in the correlation, whereas the higher-temperature data (2 °C to 25 °C) of Harlow <sup>5</sup> conformed well.

At the time of publication of the correlating paper,<sup>1</sup> we were unaware of the low-temperature results of Först and co-workers<sup>6</sup> for ordinary water which extend to -13 °C, but unfortunately these diverge by as much as 6% from those of DeFries and Jonas at high pressures. Agayev<sup>7.8</sup> has also made viscosity measurements on both isotopomers to -10°C, but to much lower pressures than the other groups. Table 1 summarizes the available high-pressure measurements, including two other sets of high-pressure data for ordinary water that overlap the range of state points reported here.<sup>9,10</sup> It is desirable to be able to test the viscosity correlation at least as well as has been done for self-diffusion, and this is best accomplished if data are available for the two isotopomers measured with the same

The high-pressure viscometer and its operation have been described elsewhere.<sup>11,12</sup> It was calibrated with Cannon standards.<sup>12</sup> Platinum-resistance thermometers newly recalibrated by the National Measurement Laboratory (CSIRO, West Lindfield, NSW) between (-65 and 100) °C on the ITS-90 to a tolerance of  $\pm 8$  mK were employed. The viscometer oil-bath temperature was controlled<sup>12</sup> to within  $\pm 0.01$  K (between -10 °C and 25 °C) and to  $\pm 0.02$  K below -10 °C. The primary pressure gauge (400 MPa Heise CM) was calibrated^{11} against a deadweight tester to  $\pm 0.05\%$  and pressures have an overall uncertainty of  $\pm 0.2$  MPa.

The working equation for the falling-body viscometer  $is^{\rm 11,13,14}$ 

$$\eta(p,T) = \frac{t(1-\rho/\rho_s)}{A[(1+2\alpha(T-T_{\rm ref}))][1-2\beta(p-p_{\rm ref})/3]}$$
(3)

where *t* is the fall time,  $\rho$  the density of the fluid,  $\rho_s$  the density of the sinker,  $\alpha$  the coefficient of thermal expansion (1.6 × 10<sup>-5</sup> K<sup>-1</sup>), and  $\beta$  the bulk compressibility (2 × 10<sup>-6</sup>

**Figure 3.** (a) Comparison of Harlow's data<sup>5</sup> for ordinary water (estimated uncertainty 1.4%) with the results of this work. Pa<sup>-1</sup>) of the sinker and tube material, in this case, 316 stainless steel. *A* is the calibration constant, 28 707 Pa<sup>-1</sup>,  $\pm 0.17\%^{12}$ , obtained at temperature  $T_{\rm ref}$  and pressure  $p_{\rm ref}$ , valid for Re < 1000. <sup>11</sup> The sinker density was corrected for changes in *T* and *p* from the calibration state point,  $T_{\rm ref} = 298.15$  K and  $p_{\rm ref} = 0.1$  MPa using the relation<sup>15</sup>

$$\rho_{\rm s} = \frac{\rho_{\rm s}(T_{\rm ref}, p_{\rm ref})}{[1 + 3\alpha(T - T_{\rm ref})][1 - \beta(p - p_{\rm ref})]} \tag{4}$$

The tube and sinker diameters are 6.5 mm and 6.3 mm, respectively. The overall uncertainty in the viscosity, based

on replicate measurements and the sum of the uncertainty in the calibration ( $\pm 0.2\%$ ) and that in the fit to the function of temperature and density described below ( $\pm 0.3\%$ ), is estimated at  $\pm 1\%$ .

Calculation of the viscosity from fall times requires knowledge of the density as a function of *T* and *p*. The equations of state recommended by the International Association for Water and Steam (IAWPS) were used to obtain the densities of  $H_2O^{17}$  and  $D_2O^{16}$  at the experimental state points. These equations are recommended for temperatures above the normal freezing points and for pressures to 100 MPa, though they can be employed outside these limits.

**Figure 4.** (a) Comparison of Harlow's data<sup>5</sup> for heavy water (estimated uncertainty  $\pm 1.4\%$ ) with the results of this work.  $\bullet$ , 10 °C;  $\blacksquare$ , 20 °C;  $\blacktriangle$ , 25 °C. (b) Comparison of the DeFries and Jonas data<sup>4</sup> for heavy water (estimated uncertainty  $\pm 2\%$ ) with the results of this work.  $\bullet$ , -15 °C;  $\blacksquare$ , -10 °C;  $\blacktriangle$ , -5 °C;  $\lor$ , 0 °C;  $\Box$ , 5 °C;  $\circ$ , 10 °C. (c) Comparison of Agayev's data<sup>7.8</sup> for heavy water (estimated uncertainty  $\pm 1.5\%$ ) with the results of this work.  $\diamondsuit$ , -9.9 °C;  $\blacklozenge$ , -7.5 °C;  $\lor$ , -4.9 °C;  $\blacktriangledown$ , -2.5 °C;  $\triangle$ , 0 °C;  $\blacktriangle$ , 2.9 °C;  $\circ$ , 3.8 °C;  $\bullet$ , 4 °C;  $\blacksquare$ , 7 °C;  $\Box$ , 10 °C.

Below the normal freezing point of water we have used the recent pVT measurements of Asada et al.<sup>18</sup> for H<sub>2</sub>O as the IAWPS correlation is largely based on the older density data of Bridgman<sup>19</sup> at subzero temperatures. The Asada data, when differentiated to yield compressibilities and thermal expansivities, are in excellent agreement with experimental measurements for these quantities.

For heavy water, the IAWPS density values at (300 to 400) MPa and below 0 °C are significantly different (1 to 2%) from those based on the data of Bridgman<sup>19</sup> used by DeFries and Jonas.<sup>4</sup> The Bridgman densities were also used for the viscosity correlation of Aleksandrov and Mateev.<sup>20</sup> It is of interest that while the IAWPS density data for heavy water can be correlated with those for light water using the Robinson approach to some (25 to 30) MPa above the limit of the IAWPS equation of state (100 MPa) at temperatures below about 40 °C,1 those of Bridgman show large deviations. Clearly new high-pressure density measurements for heavy water below the normal freezing point would be extremely useful. In the tables, we report the densities we have used in order for the viscosities to be recalculated should that be found necessary in the future.

## **Results and Discussion**

The results are presented in Tables 2 and 3.

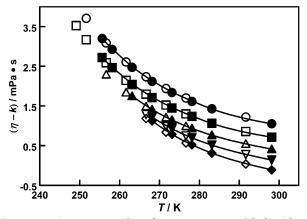

The viscosities were fitted as functions of temperature and pressure and temperature and molar volume to the empirical equation first used by Woolf<sup>21</sup>

$$\eta = \exp(a_1 + a_2 x + a_3 x/T + a_4 x^2 + a_5 x^2/T + a_6 x^3 + a_7/T + a_8/T^2)$$
(4)

where here *x* is either pressure, *p*, or molar volume, *V* (Woolf used pressure and density). The coefficients for the fits are given in Tables 4 and 5. The fit of  $\eta(T, V)$  is better than that of  $\eta(T, p)$  in each case. The residual plots for the former are shown as Figures 1 and 2.

Parts a-e of Figure 3 show a comparison of the literature data for water with our results, based on fitting the data as a function of pressure. There is excellent agreement with the data sets of Harlow,<sup>5</sup> Tanaka and co-workers,<sup>10</sup> Stanley and Batten<sup>9</sup> (except for one of the two isotherms reported for 20 °C), and Agayev.<sup>7</sup> There is also generally good agreement with the data sets of DeFries and Jonas<sup>3</sup> and of Först and co-workers,<sup>6</sup> though with some outliers, and we note that the latter group reported a divergence from the DeFries–Jonas data set at pressures higher than those covered in this work.

Parts a-c of Figure 4 show a comparison of the literature data for heavy water with our results. Again there is good agreement with the results of Harlow<sup>5</sup> and reasonable agreement with those of DeFries and Jonas<sup>4</sup> given the uncertainty in the densities referred to above, though there is some scatter between -5 °C and 5 °C. There is poor agreement with Agayev's 4 °C isotherm from his 1980 paper<sup>7</sup> but generally better agreement with his later

**Figure 5.** Comparison of isochoric viscosities of light (closed symbols) and heavy water (open symbols). The heavy water viscosities are divided by the factor 1.0544 and shifted to (T - 6.548 K). The isochores are also offset by the quantity *k* to avoid overlap.  $\bullet$ ,  $\bigcirc$ , 16 cm<sup>3</sup>/mol, k = 0 mPa·s;  $\blacksquare$ ,  $\Box$ , 16.5 cm<sup>3</sup>/mol, k = 0.25 mPa·s;  $\blacklozenge$ ,  $\triangle$ , 17 cm<sup>3</sup>/mol, k = 0.5 mPa·s;  $\checkmark$ ,  $\bigtriangledown$ , 17.5 cm<sup>3</sup>/mol, k = 1 mPa·s.

Table 4. Coefficients of Best Fit for Equation 4, x = p

	H <sub>2</sub> O	$D_2O$
<i>a</i> <sub>1</sub>	0.411 011	1.391 70
$a_2  imes 10^2/\mathrm{MPa^{-1}}$	0.854 113	1.076 27
$a_3  imes 10^{-1}$ /(K·MPa <sup>-1</sup> )	$-0.267\ 340$	-0.337597
$a_4 imes 10^4/\mathrm{MPa^{-2}}$	-0.135 750	-0.176949
$a_5 imes 10^2/(\mathrm{K}\cdot\mathrm{MPa}^{-2})$	0.525 404	0.656 687
$a_6  imes 10^8$ /MPa <sup>-3</sup>	-0.515042	$-0.534\ 170$
$a_7  imes 10^{-4}/\mathrm{K}$	$-0.235\ 032$	0.301 449
$a_8 imes 10^{-6}/\mathrm{K}^2$	0.654 401	0.783 377
standard uncertainty/(mPa·s)	0.007	0.006
standard percentage uncertainty	0.4	0.3
maximum percentage deviation	1.1	1.2

Table 5. Coefficients of Best Fit for Equation 4, x = V

	$H_2O$	$D_2O$
$a_1  imes 10^{-2}$	-0.600 113	-0.349 075
$a_2  imes 10^{-1}$ /(mol·cm <sup>-3</sup> )	0.695 355	0.357 257
$a_3  imes 10^{-4}$ /(K·mol·cm <sup>-3</sup> )	-0.373675	-0.333775
$a_4  imes 10/(\text{mol}^2 \cdot \text{cm}^{-6})$	-1.265 912	0.183 286
$a_5  imes 10^{-3}$ /(K·mol <sup>2</sup> ·cm <sup>-6</sup> )	0.116 435	0.104 781
$a_6 imes 10^2/({ m mol}^3\cdot{ m cm}^{-9})$	-0.400576	-0.579565
$a_7 imes 10^{-5}/{ m K}$	0.269 496	0.230 844
$a_8 imes 10^{-6}/\mathrm{K}^2$	0.692 075	0.779 586
standard uncertainty/(mPa·s)	0.004	0.005
standard percentage uncertainty	0.1	0.1
maximum percentage deviation	0.4	0.4

results.<sup>8</sup> The higher deviations at lower pressures, where the experimental viscosity is higher than predicted from our correlation, correspond to points taken in the supercooled region, where Agayev estimated an uncertainty of 2.5%, somewhat higher than the 1.2% given for the normal liquid region.

Comparison of the light and heavy water viscosities shows they are better fitted by the volume analogue of eq 1

$$\eta(D_2O, T/K, V) = 1.0544\eta(H_2O, (T - 6.498 \text{ K}), V)$$
 (5)

than as a function of pressure. This is shown in Figure 5; the maximum deviation is 1%. An analysis of the applicability of the Robinson conjecture to these and other data will be made in a separate article.
